1 MLE

Consider the following very simple model for stock pricing. The price at the end of each day is the price of the previous day multiplied by a fixed, but unknown, rate of return, α , with some noise, w . For a two-day period, we can observe the following sequence

$$y_2 = \alpha y_1 + w_1$$

$$y_1 = \alpha y_0 + w_0$$

where the noises w_0, w_1 are iid with the distribution $\mathcal{N}(0, \sigma^2)$, $y_0 \sim \mathcal{N}(0, \lambda)$ is independent of the noise sequence. σ^2 and λ are known, while α is unknown.

T1. Find the MLE of the rate of return α given the observed price at the end of each day, y_2, y_1, y_0 . In other words, compute for the value of α that maximizes $p(y_2, y_1, y_0 | \alpha)$.

Hint: This is a Markov process, e.g. y_2 is independent of y_0 given y_1 . In general, a process is Markov if $p(y_n | y_{n-1}, y_{n-2}, \dots) = p(y_n | y_{n-1})$. In other words, the present is independent of the past (y_{n-2}, y_{n-3}, \dots), conditioned on the immediate past y_{n-1} . You may also find the steps of the proof for logistic regression we did in class useful.

Solution. First, we can express the joint probability $p(y_2, y_1, y_0 | \alpha)$ using the Markov property:

$$p(y_2, y_1, y_0 | \alpha) = p(y_2 | y_1, \alpha) \times p(y_1 | y_0, \alpha) \times p(y_0)$$

Next, we can write down the conditional probabilities based on the model:

1. The conditional probability $p(y_2 | y_1, \alpha)$ is given by the Gaussian distribution:

$$p(y_2 | y_1, \alpha) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(y_2 - \alpha y_1)^2}{2\sigma^2}\right)$$

2. Likewise, the conditional probability $p(y_1 | y_0, \alpha)$ is:

$$p(y_1 | y_0, \alpha) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(y_1 - \alpha y_0)^2}{2\sigma^2}\right)$$

3. The prior probability $p(y_0)$ is:

$$p(y_0) = \frac{1}{\sqrt{2\pi\lambda}} \exp\left(-\frac{y_0^2}{2\lambda}\right)$$

Thus, the joint probability becomes:

$$\begin{aligned} p(y_2, y_1, y_0 | \alpha) &= p(y_2 | y_1, \alpha) \times p(y_1 | y_0, \alpha) \times p(y_0) \\ &= \frac{1}{(2\pi\sigma^2)\sqrt{2\pi\lambda}} \exp\left(-\frac{(y_2 - \alpha y_1)^2 + (y_1 - \alpha y_0)^2}{2\sigma^2} - \frac{y_0^2}{2\lambda}\right) \end{aligned}$$

We want to find the value of α that maximizes this joint probability. To do this, we can take the logarithm of the joint probability (log-likelihood):

$$\log(p(y_2, y_1, y_0 | \alpha)) = -\frac{1}{2} \log(2\pi\sigma^2) - \frac{1}{2} \log(2\pi\lambda) - \frac{(y_2 - \alpha y_1)^2 + (y_1 - \alpha y_0)^2}{2\sigma^2} - \frac{y_0^2}{2\lambda}$$

To find the MLE, we take the derivative of the log-likelihood with respect to α and set it to zero:

$$\begin{aligned} \frac{d}{d\alpha} [\log(p(y_2, y_1, y_0 | \alpha))] &= -0 - 0 - \frac{1}{2\sigma^2} [-2y_1(y_2 - \alpha y_1) - 2y_0(y_1 - \alpha y_0)] - 0 \\ 0 &= \frac{1}{\sigma^2} [(y_2 - \alpha y_1)y_1 + (y_1 - \alpha y_0)y_0] \\ 0 &= y_2 y_1 - \alpha y_1^2 + y_1 y_0 - \alpha y_0^2 \\ \alpha(y_1^2 + y_0^2) &= y_2 y_1 + y_1 y_0 \\ \alpha &= \frac{y_2 y_1 + y_1 y_0}{y_1^2 + y_0^2} \end{aligned}$$

Therefore, the MLE for α is:

$$\hat{\alpha} = \frac{y_2 y_1 + y_1 y_0}{y_1^2 + y_0^2}$$

OT1. Consider the general case, where

$$y_{n+1} = \alpha y_n + w_n, \quad n = 0, 1, 2, \dots$$

Find the MLE given the observed prices y_{N+1}, y_N, \dots, y_0 .

Solution. Just like in the two-day case, we can express the joint probability using the Markov property:

$$p(y_{N+1}, y_N, \dots, y_0 | \alpha) = p(y_{N+1} | y_N, \alpha) \times p(y_N | y_{N-1}, \alpha) \times \dots \times p(y_1 | y_0, \alpha) \times p(y_0)$$

Next, we can write down the conditional probabilities based on the model:

1. The conditional probability $p(y_{n+1} | y_n, \alpha)$ is given by the Gaussian distribution:

$$p(y_{n+1} | y_n, \alpha) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(y_{n+1} - \alpha y_n)^2}{2\sigma^2}\right)$$

2. The prior probability $p(y_0)$ is:

$$p(y_0) = \frac{1}{\sqrt{2\pi\lambda}} \exp\left(-\frac{y_0^2}{2\lambda}\right)$$

Thus, the joint probability becomes:

$$\begin{aligned} p(y_{N+1}, y_N, \dots, y_0 | \alpha) &= \prod_{n=0}^N p(y_{n+1} | y_n, \alpha) \times p(y_0) \\ &= \frac{1}{(2\pi\sigma^2)^{(N+1)/2} \sqrt{2\pi\lambda}} \exp\left(-\sum_{n=0}^N \frac{(y_{n+1} - \alpha y_n)^2}{2\sigma^2} - \frac{y_0^2}{2\lambda}\right) \end{aligned}$$

We want to find the value of α that maximizes this joint probability. To do this, we can take the logarithm of the joint probability (log-likelihood):

$$\log(p(y_{N+1}, y_N, \dots, y_0 | \alpha)) = -\frac{N+1}{2} \log(2\pi\sigma^2) - \frac{1}{2} \log(2\pi\lambda) - \sum_{n=0}^N \frac{(y_{n+1} - \alpha y_n)^2}{2\sigma^2} - \frac{y_0^2}{2\lambda}$$

To find the MLE, we take the derivative of the log-likelihood with respect to α and set it to zero:

$$\begin{aligned} \frac{d}{d\alpha} [\log(p(y_{N+1}, y_N, \dots, y_0 | \alpha))] &= - \sum_{n=0}^N \frac{1}{2\sigma^2} [-2(y_{n+1} - \alpha y_n) y_n] \\ 0 &= \sum_{n=0}^N \frac{1}{\sigma^2} (y_{n+1} - \alpha y_n) y_n \\ 0 &= \sum_{n=0}^N y_{n+1} y_n - \alpha \sum_{n=0}^N y_n^2 \\ \alpha \sum_{n=0}^N y_n^2 &= \sum_{n=0}^N y_{n+1} y_n \\ \alpha &= \frac{\sum_{n=0}^N y_{n+1} y_n}{\sum_{n=0}^N y_n^2} \end{aligned}$$

Therefore, the MLE for α in the general case is:

$$\hat{\alpha} = \frac{\sum_{n=0}^N y_{n+1} y_n}{\sum_{n=0}^N y_n^2}$$

2 Simple Bayes Classifier

A student in Pattern Recognition course had finally built the ultimate classifier for cat emotions. He used one input features: the amount of food the cat ate that day, x (Being a good student he already normalized x to standard Normal). He proposed the following likelihood probabilities for class 1 (happy cat) and 2 (sad cat)

$$P(x | w_1) = \mathcal{N}(4, 2)$$

$$P(x | w_2) = \mathcal{N}(0, 2)$$

Figure 1: The sad cat and the happy cat used in training.

T2. Plot the posteriors values of the two classes on the same axis. Using the likelihood ratio test, what is the decision boundary for this classifier? Assume equal prior probabilities.

Solution. First, we can calculate the posterior probabilities for each class using Bayes' theorem:

$$P(w_1 | x) = \frac{P(x | w_1)P(w_1)}{P(x)}$$

$$P(w_2 | x) = \frac{P(x | w_2)P(w_2)}{P(x)}$$

Assume equal prior probabilities:

$$P(w_1) = P(w_2)$$

The likelihood ratio test compares the posterior probabilities:

$$\frac{P(w_1 | x)}{P(w_2 | x)} = \frac{P(x | w_1)P(w_1)}{P(x | w_2)P(w_2)}$$

$$\frac{P(w_1 | x)}{P(w_2 | x)} = \frac{P(x | w_1)}{P(x | w_2)}$$

To find the decision boundary, we set the likelihood ratio equal to 1:

$$\frac{P(x | w_1)}{P(x | w_2)} = 1$$

$$P(x | w_1) = P(x | w_2)$$

Substituting the Gaussian likelihoods:

$$\frac{1}{\sqrt{2\pi \cdot 2}} \exp\left(-\frac{(x-4)^2}{2 \cdot 2}\right) = \frac{1}{\sqrt{2\pi \cdot 2}} \exp\left(-\frac{x^2}{2 \cdot 2}\right)$$

$$\exp\left(-\frac{(x-4)^2}{4}\right) = \exp\left(-\frac{x^2}{4}\right)$$

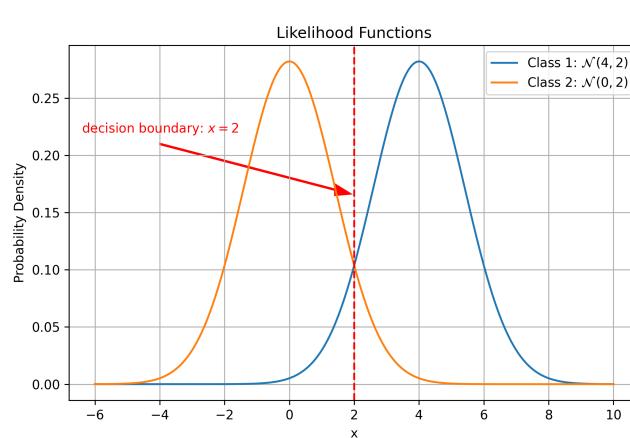

$$-\frac{(x-4)^2}{4} = -\frac{x^2}{4}$$

$$(x-4)^2 = x^2$$

$$x = 2$$

Thus, the decision boundary for this classifier is at $x = 2$.

Using Python, we can plot the posterior probabilities for both classes:

T3. What happens to the decision boundary if the cat is happy with a prior of 0.75?

Solution. With the new prior probabilities:

$$P(w_1) = 0.75 \text{ and } P(w_2) = 0.25$$

The likelihood ratio test now becomes:

$$\begin{aligned} \frac{P(w_1 | x)}{P(w_2 | x)} &= \frac{P(x | w_1)P(w_1)}{P(x | w_2)P(w_2)} \\ \frac{P(w_1 | x)}{P(w_2 | x)} &= \frac{P(x | w_1) \cdot (0.75)}{P(x | w_2) \cdot (0.25)} \\ \frac{P(w_1 | x)}{P(w_2 | x)} &= 3 \left(\frac{P(x | w_1)}{P(x | w_2)} \right) \end{aligned}$$

To find the decision boundary, we set the likelihood ratio equal to 1:

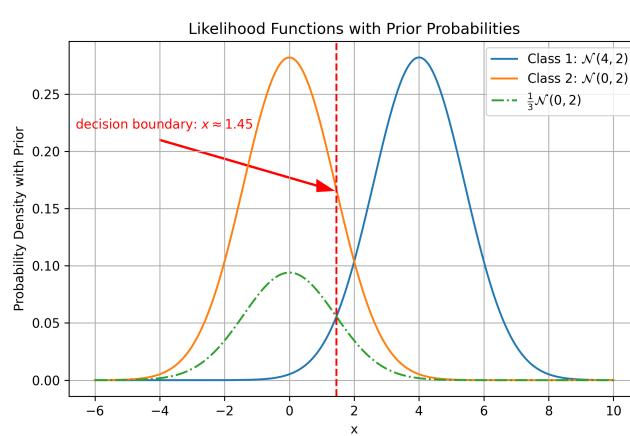

$$\begin{aligned} 3 \left(\frac{P(x | w_1)}{P(x | w_2)} \right) &= 1 \\ P(x | w_1) &= \frac{1}{3} P(x | w_2) \end{aligned}$$

Substituting the Gaussian likelihoods:

$$\begin{aligned} \frac{1}{\sqrt{2\pi \cdot 2}} \exp \left(-\frac{(x-4)^2}{2 \cdot 2} \right) &= \frac{1}{3} \times \frac{1}{\sqrt{2\pi \cdot 2}} \exp \left(-\frac{x^2}{2 \cdot 2} \right) \\ \exp \left(-\frac{(x-4)^2}{4} \right) &= \frac{1}{3} \times \exp \left(-\frac{x^2}{4} \right) \\ -\frac{(x-4)^2}{4} &= \ln \left(\frac{1}{3} \right) - \frac{x^2}{4} \\ (x-4)^2 &= x^2 + 4 \ln(3) \\ x &= 2 - \frac{\ln(3)}{2} \\ x &\approx 1.45 \end{aligned}$$

Thus, the decision boundary for this classifier is at $x \approx 1.45$.

Using Python, we can plot the posterior probabilities for both classes:

This shows that the decision boundary has shifted to the left due to the increased prior probability of the happy cat class (as shown by the orange line in the figure above).

OT2. For the ordinary case of $P(x | w_1) = \mathcal{N}(\mu_1, \sigma^2)$, $P(x | w_2) = \mathcal{N}(\mu_2, \sigma^2)$, $p(w_1) = p(w_2) = 0.5$, prove that the decision boundary is at $x = \frac{\mu_1 + \mu_2}{2}$.

Proof. For the ordinary case, we have:

$$P(x | w_1) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x - \mu_1)^2}{2\sigma^2}\right)$$

$$P(x | w_2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x - \mu_2)^2}{2\sigma^2}\right)$$

Using Bayes' theorem, the posterior probabilities for each class are:

$$P(w_1 | x) = \frac{P(x | w_1)P(w_1)}{P(x)}$$

$$P(w_2 | x) = \frac{P(x | w_2)P(w_2)}{P(x)}$$

Because the equality of prior probabilities:

$$P(w_1) = P(w_2) = 0.5$$

The likelihood ratio test compares the posterior probabilities:

$$\frac{P(w_1 | x)}{P(w_2 | x)} = \frac{P(x | w_1)P(w_1)}{P(x | w_2)P(w_2)}$$

$$\frac{P(w_1 | x)}{P(w_2 | x)} = \frac{P(x | w_1)}{P(x | w_2)}$$

To find the decision boundary, we set the likelihood ratio equal to 1:

$$\frac{P(x | w_1)}{P(x | w_2)} = 1$$

$$P(x | w_1) = P(x | w_2)$$

Substituting the Gaussian likelihoods:

$$\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x - \mu_1)^2}{2\sigma^2}\right) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x - \mu_2)^2}{2\sigma^2}\right)$$

$$\exp\left(-\frac{(x - \mu_1)^2}{2\sigma^2}\right) = \exp\left(-\frac{(x - \mu_2)^2}{2\sigma^2}\right)$$

$$-\frac{(x - \mu_1)^2}{2\sigma^2} = -\frac{(x - \mu_2)^2}{2\sigma^2}$$

$$(x - \mu_1)^2 = (x - \mu_2)^2$$

$$0 = (x - \mu_2)^2 - (x - \mu_1)^2$$

$$0 = ((x - \mu_2) - (x - \mu_1))((x - \mu_2) + (x - \mu_1))$$

$$0 = (\mu_1 - \mu_2)(2x - (\mu_1 + \mu_2))$$

$$0 = (2x - (\mu_1 + \mu_2)) ; \text{ because } \mu_1 \neq \mu_2$$

$$x = \frac{\mu_1 + \mu_2}{2}$$

Thus, the decision boundary for this classifier is at $x = \frac{\mu_1 + \mu_2}{2}$.

OT3. If the student changed his model to

$$P(x | w_1) = \mathcal{N}(4, 2)$$

$$P(x | w_2) = \mathcal{N}(0, 4)$$

Plot the posteriors values of the two classes on the same axis. What is the decision boundary for this classifier? Assume equal prior probabilities.

Solution. Like the previous problems, we can calculate the posterior probabilities for each class using Bayes' theorem, assume the equality of prior probabilities, we know that:

$$\frac{P(x | w_1)}{P(x | w_2)} = 1$$

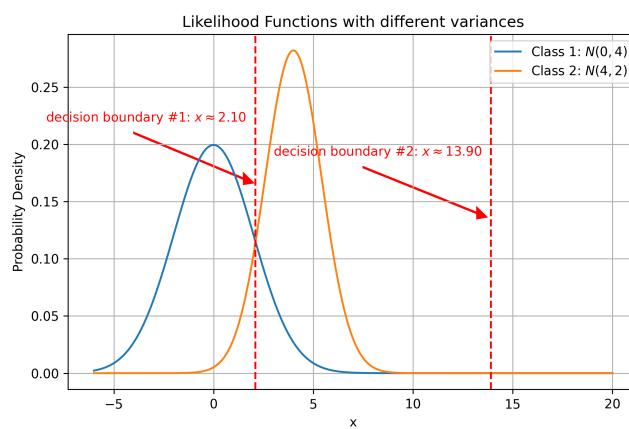

$$P(x | w_1) = P(x | w_2)$$

Substituting the Gaussian likelihoods:

$$\begin{aligned} \frac{1}{\sqrt{2\pi \cdot 2}} \exp\left(-\frac{(x-4)^2}{2 \cdot 2}\right) &= \frac{1}{\sqrt{2\pi \cdot 4}} \exp\left(-\frac{x^2}{2 \cdot 4}\right) \\ \exp\left(-\frac{(x-4)^2}{4}\right) &= \frac{1}{\sqrt{2}} \times \exp\left(-\frac{x^2}{8}\right) \\ -\frac{(x-4)^2}{4} &= -\frac{1}{2} \ln(2) - \frac{x^2}{8} \\ (x-4)^2 &= \frac{x^2}{2} + 2 \ln(2) \\ x^2 - 8x + 16 &= \frac{x^2}{2} + 2 \ln(2) \\ \frac{x^2}{2} - 8x + (16 - 2 \ln(2)) &= 0 \\ x &= \frac{8 \pm \sqrt{64 - 2(16 - 2 \ln(2))}}{1} \\ x &\approx 2.10, 13.90 \end{aligned}$$

Thus, the decision boundary for this classifier is at $x \approx 2.10, 13.90$.

Using Python, we can plot the posterior probabilities for both classes:

3 Employee Attrition Prediction

If Cats Were in a Corporate World

Figure 2: Pictures of employees cats not used in this dataset.

In this part of the homework, we will work on employee attrition prediction using data from Kaggle IBM HR Analytics Employee Attrition & Performance.

The data

For each employee, 34 features are provided. We will use these features to predict each employee attrition e.g whether the employee will leave the company (**yes** for leaving, **no** for staying)

Notable features are:

- **Education:** 1 ‘Below College’, 2 ‘College’, 3 ‘Bachelor’, 4 ‘Master’, 5 ‘Doctor’.
- **Environment Satisfaction:** 1 ‘Low’, 2 ‘Medium’, 3 ‘High’, 4 ‘Very High’.
- **Job Involvement:** 1 ‘Low’, 2 ‘Medium’, 3 ‘High’, 4 ‘Very High’.
- **Job Satisfaction:** 1 ‘Low’, 2 ‘Medium’, 3 ‘High’, 4 ‘Very High’.
- **Performance Rating:** 1 ‘Low’, 2 ‘Good’, 3 ‘Excellent’, 4 ‘Outstanding’.
- **Relationship Satisfaction:** 1 ‘Low’, 2 ‘Medium’, 3 ‘High’, 4 ‘Very High’.
- **WorkLifeBalance:** 1 ‘Bad’, 2 ‘Good’, 3 ‘Better’, 4 ‘Best’.

The database

First let's look at the given data file `hr-employee-attrition-with-null.csv`. Load the data using pandas. Use `describe()` and `head()` to get a sense of what the data is like. Our target of prediction is Attrition. Other columns are our input features.

Data cleaning

There are many missing values in this database. They are represented with `NaN`. In the previous homework, we filled the missing values with the mean, median, or mode values. That is because classifiers such as logistic regression cannot deal with missing feature values. However, for the case of Naive Bayes which we will use in this homework compares $\prod_i p(x_i | \text{class})$ and treat each x_i as independent features. Thus, if a feature i is missing, we can drop that term from the comparison without having to guess what the missing feature is. First, convert the yes and no in this data table to 1 and 0. Then, we have to convert each categorical feature to number.

```

1 all.loc[all["Attrition"] == "no", "Attrition"] = 0.0
2 all.loc[all["Attrition"] == "yes", "Attrition"] = 1.0
3 for col in cat_cols:
4     all[col] = pd.Categorical(all[col]).codes

```

We will also drop the employee numbers.

```
1 all = all.drop(columns = "EmployeeNumber")
```

There is no standard rule on how much data you should segment into as training and test set. But for now let's use 90% training 10% testing. Select 10% from the “Attrition == yes” and 10% from the “Attrition == no” as your testing set, `test_set`. Then, use the rest of the data as your training set, `train_set`.

Histogram discretization

In class, we learned that in order to create a Bayes Classifier we first need to estimate the posterior or likelihood probability distributions. The simplest way to estimate probability distributions is via histograms. To do histogram estimation, we divide the entire data space into a finite number of bins. Then, we count how many data points are there in each bin and normalize using the total number of data points (so that the probability sums to 1). Since we are grouping a continuous valued feature into a finite number of bins, we can also call this process, discretization.

The following code create a histogram of a column `col` from `train_set`.

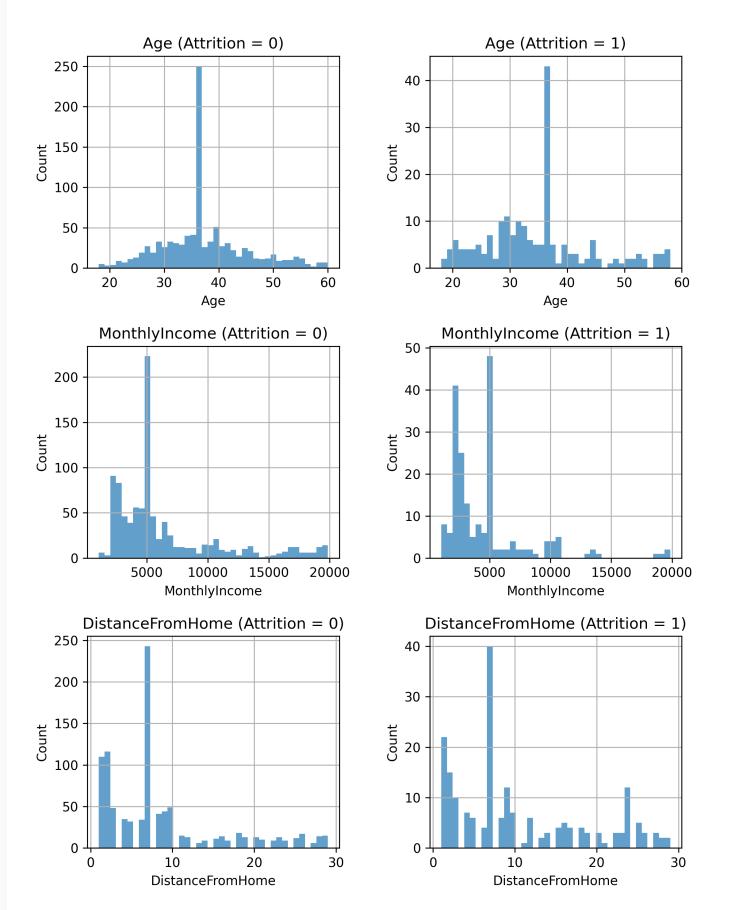

```

1 train_col_no_nan = train_set[~np.isnan(train_set[col])]
2 # remove NaN values
3
4 # bin the data into 40 equally spaced bins
5 # hist is the count for each bin
6 # bin_edge is the edge values of the bins
7 hist, bin_edge = np.histogram(train_col_no_nan, 40)
8
9 # make sure to import matplotlib.pyplot as plt
10 # plot the histogram
11 plt.fill_between(bin_edge.repeat(2)[1:-1], hist.repeat(2),
12                  facecolor='steelblue')
13 plt.show()

```

T4. Observe the histogram for `Age`, `MonthlyIncome` and `DistanceFromHome`. How many bins have zero counts? Do you think this is a good discretization? Why?

Solution. Using the provided code, we can plot the histograms for the features `Age`, `MonthlyIncome`, and `DistanceFromHome`. After plotting the histograms, we can count the number of bins with zero counts.

The number of bins with zero counts for each feature is as follows:

- `Age`: 0 (Attrition = 0) + 2 (Attrition = 1) = 2 bins
- `MonthlyIncome`: 0 (Attrition = 0) + 14 (Attrition = 1) = 14 bins
- `DistanceFromHome`: 11 (Attrition = 0) + 11 (Attrition = 1) = 22 bins

Having bins with zero counts indicates that there are ranges of values for these features that are not represented in the training data. This can be problematic for a histogram-based model, as it may lead to poor generalization when making predictions on new data. If a new data point falls into a bin with zero counts, the model will not have any information to estimate the probability for that feature value.

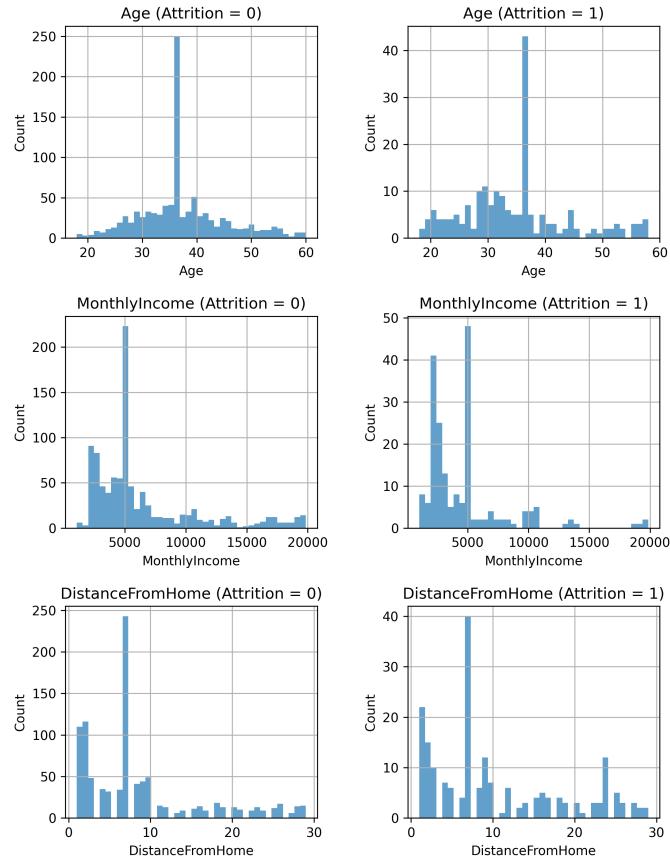

Therefore, this discretization may not be ideal, especially for features like `MonthlyIncome` and `DistanceFromHome`, where a significant number of bins have zero counts. To improve the discretization, we could consider using a different number of bins or employing techniques such as Gaussian Mixture Models (GMMs) to better capture the underlying distribution of the data.

T5. Can we use a Gaussian to estimate this histogram? Why? What about a Gaussian Mixture Model (GMM)?

Solution. To determine whether we can use a Gaussian to estimate the histogram for the features `Age`, `MonthlyIncome`, and `DistanceFromHome`, we need to analyze the shape of the histograms.

A Gaussian distribution is characterized by its bell-shaped curve, which is symmetric around the mean. If the histogram of a feature closely resembles this bell-shaped curve, then it may be appropriate to use a Gaussian to estimate the distribution of that feature.

Upon examining the histograms:

- **Age:** The histogram appears to be roughly bell-shaped, suggesting that a Gaussian distribution could be a reasonable approximation.
- **MonthlyIncome:** The histogram is skewed and does not resemble a bell-shaped curve, indicating that a Gaussian may not be suitable for this feature.
- **DistanceFromHome:** The histogram is also skewed and does not resemble a bell-shaped curve, suggesting that a Gaussian may not be appropriate for this feature either.

A Gaussian Mixture Model (GMM) is a more flexible approach that can model complex distributions by combining multiple Gaussian components. If the histogram of a feature shows multiple peaks or is skewed, a GMM can better capture the underlying distribution.

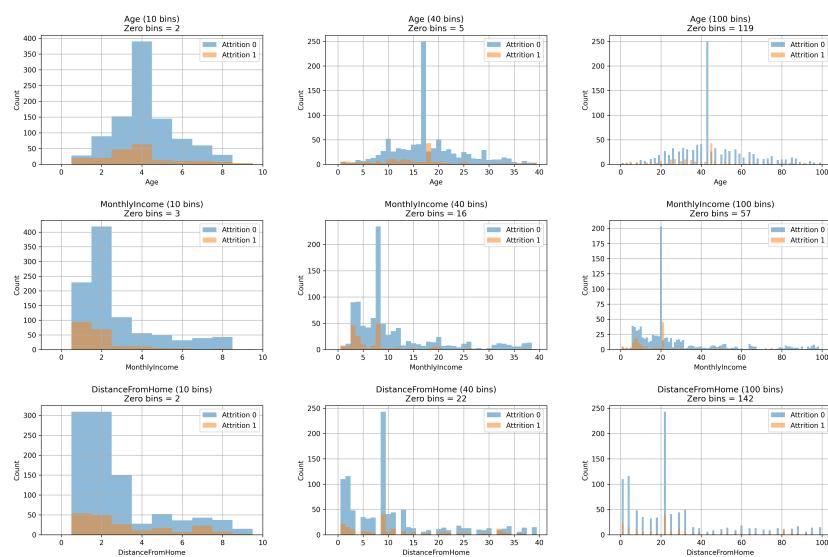

The above discretization equally segments the space into equally spaced bins. This is the best method to segment if you know nothing about the data. Still, doing so may leave us with many bins with zero counts when we have too little data. To prevent this issue, we might assume that the distribution of our data is Normal then draw the probabilities of each data point from this distribution instead. We will do this later. For now, do

1. First set the number of bins to 10 for `Age`, `MonthlyIncome` and `DistanceFromHome`. **Make numbers of bin a parameter as we will change this later.**
2. Bin each values in the training set into bins using the function `np.digitize`, then count the number in each bins using `np.bincount`. Be careful with the maximum and minimum values, your first bin should cover `-inf`, and your final bin should cover `inf`, so that you can handle test data that might be outside of the minimum and maximum values.

You do not need to submit anything for this task. You might want to make this a function so that you can change the number of bins.

T6. Now plot the histogram according to the method described above (with 10, 40, and 100 bins) and show 3 plots each for `Age`, `MonthlyIncome`, and `DistanceFromHome`. Which bin size is most sensible for each features? Why?

Solution. Using the method described, we can plot the histograms for the features `Age`, `MonthlyIncome`, and `DistanceFromHome` with different bin sizes (10, 40, and 100 bins).

After analyzing the histograms with different bin sizes, we can determine the most sensible bin size for each feature:

- **Age:** A bin size of 10 seems most sensible as it captures the overall distribution without being too granular.
- **MonthlyIncome:** A bin size of 10 appears to be the most appropriate, as it provides a good balance between detail and generalization, capturing the skewness of the distribution, also it have least empty bins.
- **DistanceFromHome:** A bin size of 10 also seems most sensible, as it captures the distribution without being too granular, and it has fewer empty bins compared to larger bin sizes.

T7. For the rest of the features, which one should be discretized in order to be modeled by histograms? What are the criteria for choosing whether we should discretize a feature or not? Answer this and discretize those features into 10 bins each. In other words, figure out the `bin_edge` for each feature, then use `digitize()` to convert the features to discrete values.

Solution. To determine which features should be discretized for modeling with histograms, we can consider the following criteria:

- The feature is continuous and has a different distribution for different classes (Attrition = 0 vs 1).
- Features that are already categorical or have a small number of unique values may not need to be discretized, as they can be directly modeled using histograms without further binning.

Based on these criteria, considering the following histograms and the nature of the features, we can decide which features to discretize:

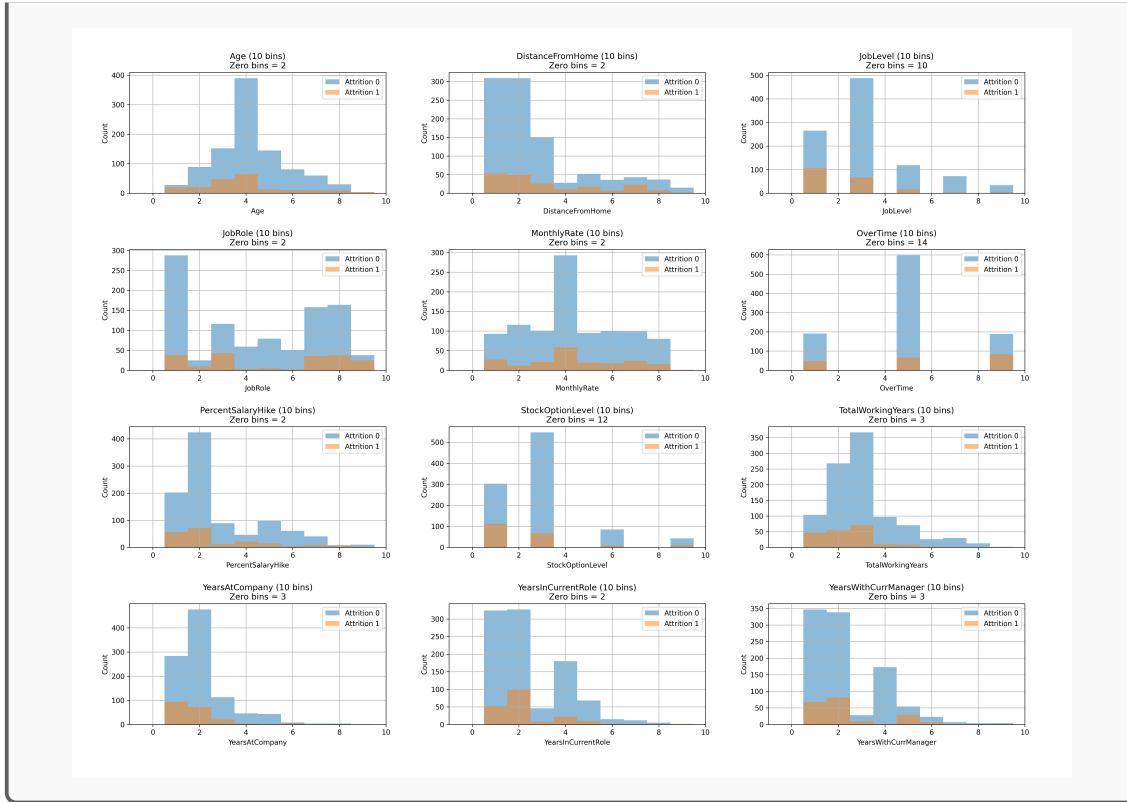

After analyzing the histograms and the nature of the features, we can choose to discretize the following features:

`Age, DistanceFromHome, JobLevel, JobRole, MonthlyRate, OverTime,
PercentSalaryHike, StockOptionLevel, TotalWorkingYears, YearsAtCompany,
YearsInCurrentRole, YearsWithCurrManager`

For each of these features, we can calculate the bin edges using the minimum and maximum values of the feature in the training set, and then use `np.digitize()` to convert the continuous values into discrete bin indices.

The resulting histograms after discretization will look like this:

The MLE for the likelihood distribution of discretized histograms

We would like to build a Naive Bayes classifier which compares the posterior $p(\text{leave} \mid x_i)$ against $p(\text{stay} \mid x_i)$. However, figuring out $p(\text{class} \mid x_i)$ is often hard (not true for this case). Thus, we turn to the likelihood $p(x_i \mid \text{class})$, which can be derived from the discretized histograms.

T8. What kind of distribution should we use to model histograms? (Answer a distribution name) What is the MLE for this likelihood distribution? (Describe how to do the MLE). Plot the likelihood distributions of `MonthlyIncome`, `JobRole`, `HourlyRate`, and `MaritalStatus` for different Attrition values.

Hint: In class we talk about how a fair coin can be modeled using the Bernoulli distribution. A histogram is very similar to a dice in the sense that the outcome is a set of possibilities.

Proof. We are going to show that the MLE for the likelihood distribution of a categorical distribution is given by the normalized counts of each category. Consider a categorical distribution with k categories, where the probability of each category i is denoted as p_i .

Given a dataset with n samples, where n_i samples belong to category i , the likelihood function can be expressed as:

$$L(p_1, p_2, \dots, p_k) = \prod_{i=1}^k p_i^{n_i}$$

To find the MLE, we need to maximize this likelihood function with respect to the probabilities p_i , subject to the constraint that the probabilities sum to 1:

$$\sum_{i=1}^k p_i = 1$$

We can use the method of **Lagrange multipliers** to incorporate this constraint into our optimization problem. The Lagrangian function can be defined as:

$$\mathcal{L}(p_1, p_2, \dots, p_k, \lambda) = \prod_{i=1}^k p_i^{n_i} + \lambda \left(1 - \sum_{i=1}^k p_i \right)$$

Taking the logarithm of the likelihood function to simplify the optimization, we get:

$$\log L(p_1, p_2, \dots, p_k) = \sum_{i=1}^k n_i \log p_i$$

Now, we can take the partial derivatives of the Lagrangian with respect to p_i and λ and set them to zero:

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial p_i} &= \frac{n_i}{p_i} - \lambda = 0 \quad \text{for } i = 1, 2, \dots, k \\ \frac{\partial \mathcal{L}}{\partial \lambda} &= 1 - \sum_{i=1}^k p_i = 0\end{aligned}$$

From the first set of equations, we can express p_i in terms of λ :

$$p_i = \frac{n_i}{\lambda}$$

Substituting this into the second equation, we get:

$$\begin{aligned}1 &= \sum_{i=1}^k p_i \\ 1 &= \sum_{i=1}^k \frac{n_i}{\lambda} \\ 1 &= \frac{1}{\lambda} \sum_{i=1}^k n_i \\ 1 &= \frac{n}{\lambda} \\ \lambda &= n\end{aligned}$$

Substituting back into the expression for p_i , we get the MLE for the probabilities:

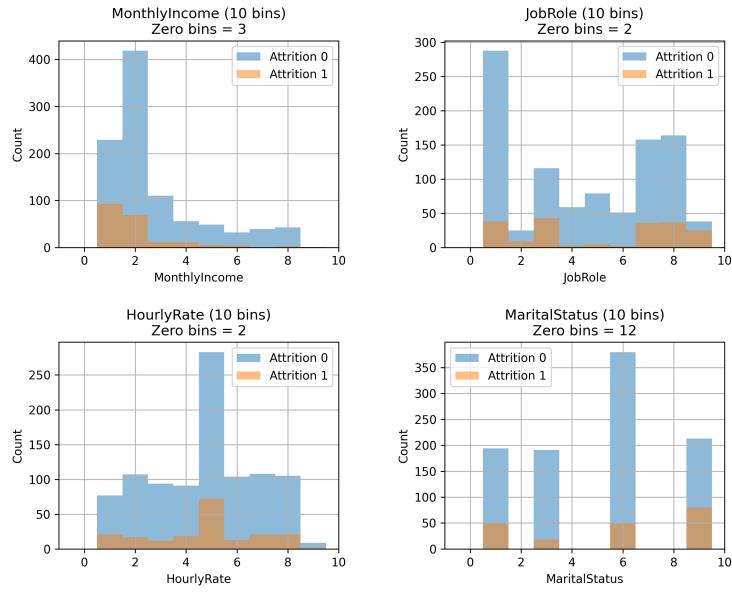

$$p_i = \frac{n_i}{n}$$

Thus, the MLE for the likelihood distribution of a **categorical distribution** is given by the normalized counts of each category, which can be interpreted as the empirical probability of each category in the dataset.

Solution. The distribution that we can use to model histograms is the **categorical distribution**. Since we have discretized the features into a finite number of bins, we can treat each bin as a category.

The MLE for the likelihood distribution of a categorical distribution can be calculated by $p_i = \frac{n_i}{n}$, where n_i is the count of samples in category i (or bin i) and n is the total number of samples.

The plot of the likelihood distributions of `MonthlyIncome`, `JobRole`, `HourlyRate`, and `MaritalStatus` are shown below for different Attrition values:

T9. What is the prior distribution of the two classes?

Solution. The prior distribution of the two classes can be calculated by counting the number of samples in each class (`Attrition` = 0 and `Attrition` = 1) in the training set and normalizing by the total number of samples.

Let n_0 be the number of samples with `Attrition` = 0 (staying) and n_1 be the number of samples with `Attrition` = 1 (leaving). The total number of samples is $n = n_0 + n_1$.

After counting the samples in the training set, we find that:

$$\begin{array}{c|c} \text{Attrition} = 0 \text{ (staying)} & \text{Attrition} = 1 \text{ (leaving)} \\ \hline n_0 = 978 & n_1 = 198 \end{array}$$

Thus, the total number of samples is $n = 978 + 198 = 1176$.

The prior probabilities for each class can be calculated as follows:

$$p(\text{stay}) = \frac{n_0}{n} = \frac{978}{978 + 198} \approx 0.832$$

$$p(\text{leave}) = \frac{n_1}{n} = \frac{198}{978 + 198} \approx 0.168$$

Naive Bayes classification

We are now ready to build our Naive Bayes classifier. Which makes a decision according to

$$H(x) = \frac{p(\text{leave})}{p(\text{stay})} \prod_{i=1} p(x_i | \text{leave}) / p(x_i | \text{stay})$$

If $H(x)$ is larger than 1, then classify it as `leave`.

If $H(x)$ is smaller than 1, then classify it as `stay`.

Note we often work in the log scale to prevent floating point underflow. In other words,

$$lH(x) = \log(p(\text{leave})) - \log(p(\text{stay})) + \sum_{i=1} [\log(p(x_i | \text{leave})) - \log(p(x_i | \text{stay}))]$$

If $lH(x)$ is larger than 0, then classify it as `leave`. If $lH(x)$ is smaller than 0, then classify it as `stay`.

T10. If we use the current Naive Bayes with our current Maximum Likelihood Estimates, we will find that some $P(x_i | \text{attrition})$ will be zero and will result in the entire product term to be zero. Propose a method to fix this problem.

Solution. The problem of zero probabilities in Naive Bayes can be addressed using a technique called **Laplace smoothing** (also known as add-one smoothing). Laplace smoothing works by adding a small constant (usually 1) to the count of each category in the likelihood estimation. This way, even if a category has zero counts in the training data, it will still have a non-zero probability.

T11. Implement your Naive Bayes classifier. Use the learned distributions to classify the `test_set`. Don't forget to allow your classifier to handle missing values in the test set. Report the overall Accuracy. Then, report the Precision, Recall, and F1 score for detecting attrition. See Lecture 1 for the definitions of each metric.

Solution. The reporting of the overall Accuracy, Precision, Recall, and F1 score for detecting attrition in `test_set` using the Naive Bayes classifier (histogram-based) are as follows:

Metric	Value
Accuracy	0.8605
Precision (Attrition = 1)	0.4667
Recall (Attrition = 1)	0.3590
F1 Score (Attrition = 1)	0.4058

Probability density function

Now, instead of using histogram discretization, we will assume that our features are normally distributed. In other words, for certain feature types, $P(x_i | \text{attrition})$ is now Normally distributed. By doing so, we can estimate the mean and standard deviation for each feature and compute the probability of each test feature by using the Gaussian probability density function instead. You can do this by calling:

```
1  scipy.stats.norm(mean, std).pdf(feature_value)
```

T12. Use the learned distributions to classify the `test_set`. Report the results using the same metric as the previous question.

Solution. The reporting of the overall Accuracy, Precision, Recall, and F1 score for detecting attrition in `test_set` using the Naive Bayes classifier (Gaussian-based) are as follows:

Metric	Value
Accuracy	0.8197
Precision (Attrition = 1)	0.3600
Recall (Attrition = 1)	0.4615
F1 Score (Attrition = 1)	0.4045

Baseline comparison

In machine learning, we need to be able to evaluate how good our model is. We usually compare our model with a different model and show that our model is better. Sometimes we do not have a candidate model to evaluate our method against. In this homework, we will look at two simple baselines, the random choice, and the majority rule.

T13. The random choice baseline is the accuracy if you make a random guess for each test sample. Give random guess (50% leaving, and 50% staying) to the test samples. Report the overall Accuracy. Then, report the Precision, Recall, and F1 score for attrition prediction using the random choice baseline.

Solution. The results for the random choice baseline are as follows:

Metric	Value
Accuracy	0.5544
Precision (Attrition = 1)	0.1761
Recall (Attrition = 1)	0.6410
F1 Score (Attrition = 1)	0.2762

T14. The majority rule is the accuracy if you use the most frequent class from the training set as the classification decision. Report the overall Accuracy. Then, report the Precision, Recall, and F1 score for attrition prediction using the majority rule baseline.

Solution. The results for the majority rule baseline are as follows:

Metric	Value
Accuracy	0.8673
Precision (Attrition = 1)	0.0000
Recall (Attrition = 1)	0.0000
F1 Score (Attrition = 1)	0.0000

T15. Compare the two baselines with your Naive Bayes classifier.

Solution. Comparing the Naive Bayes classifier with the two baselines (random choice and majority rule), we can see the following results:

Metric	Naive Bayes (Histogram)	Random Choice	Majority Rule
Accuracy	0.8605	0.5544	0.8673
Precision	0.4667	0.1761	0.0000
Recall	0.3590	0.6410	0.0000
F1 Score	0.4058	0.2762	0.0000

We can compare the results as follows:

- The Naive Bayes classifier outperforms the random choice baseline in terms of Accuracy, Precision, Recall, and F1 Score.
- The majority rule baseline has a slightly higher Accuracy than the Naive Bayes classifier, but it fails to predict any positive cases ($\text{Attrition} = 1$), resulting in a Precision, Recall, and F1 Score of 0 for attrition prediction.

This highlights the importance of considering multiple evaluation metrics when comparing classifiers, as a high Accuracy does not necessarily indicate good performance in predicting the minority class ($\text{Attrition} = 1$ in this case).

Threshold finding

In practice, instead of comparing $lH(x)$ against 0, we usually compare against a threshold, t . We can change the threshold so that we maximize the accuracy, precision, recall, or F1 score (depending on which measure we want to optimize).

T16. Use the following threshold values

```
1 t = np.arange(-5, 5, 0.05)
```

find the best accuracy, and F1 score (and the corresponding thresholds)

Solution. After evaluating the Naive Bayes classifier with different threshold values, we can find the best accuracy and F1 score along with their corresponding thresholds.

Metric	Best Value	Corresponding Threshold
Accuracy	0.8776	1.65
F1 Score	0.4179	0.15

Receiver Operating Characteristic (RoC) curve

The recall rate (true positive rate) and the false alarm rate can change as we vary the threshold. The false alarm rate will deteriorate as we decrease the threshold (more false alarms). On the other hand, the recall rate will improve. This is also another trade-off machine learning practitioners need to consider. If we plot the false alarm vs recall as we vary the threshold (false alarm as the x-axis and recall as the y-axis), we get a plot called the “Receiver operating characteristic (RoC) curve.” The RoC curve illustrates the performance of a binary classifier (Will this person leave? Will this person survive the Titanic? yes or no) as the threshold is varied. An example RoC curve is shown below

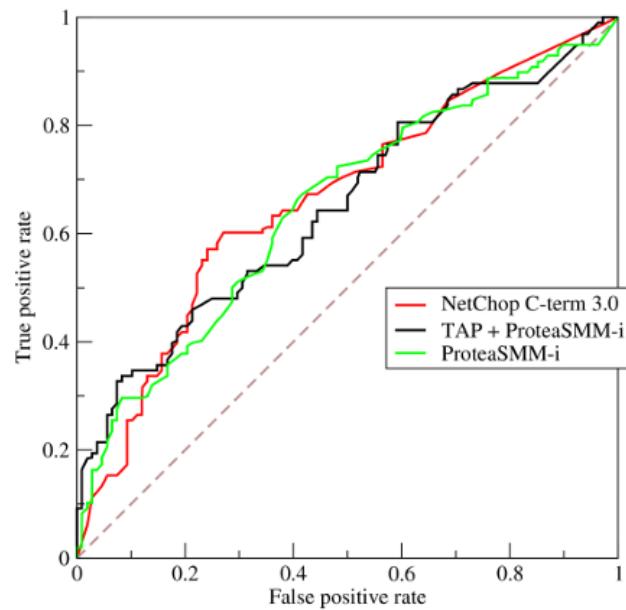

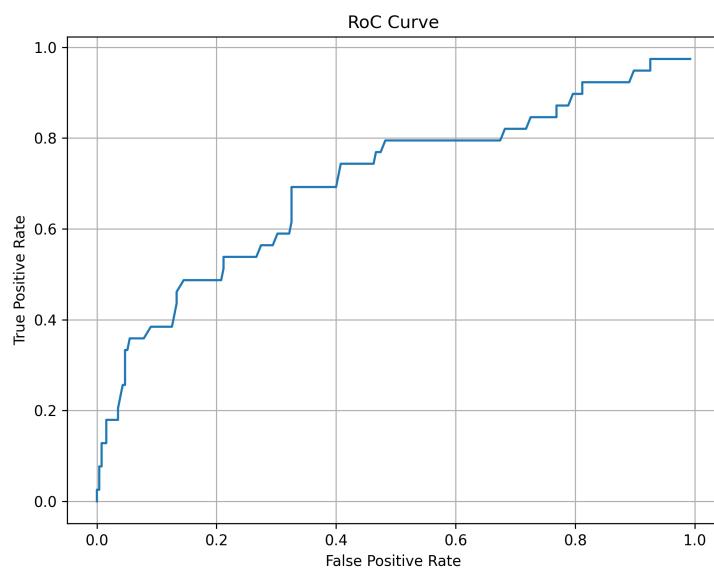

Figure 3: An example RoC curve. Source [wikipedia](#)

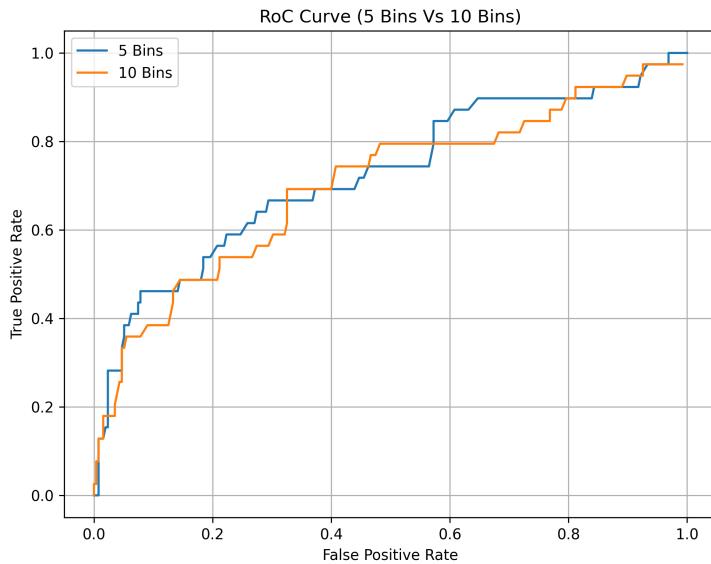

T17. Plot the RoC of your classifier.

Solution. The RoC curve for the Naive Bayes classifier is plotted below:

T18. Change the number of discretization bins to 5. What happens to the RoC curve? Which discretization is better? The number of discretization bins can be considered as a hyperparameter, and must be chosen by comparing the final performance.

Solution. The RoC curve for the Naive Bayes classifier with 5 discretization bins is plotted below:

After comparing the RoC curves for the Naive Bayes classifier with 10 bins and 5 bins, we can see that the curve with 10 bins has a higher area under the curve (AUC) compared to the curve with 5 bins. This indicates that the Naive Bayes classifier with 10 bins has better performance in distinguishing between the two classes (Attrition = 0 and Attrition = 1) than the classifier with 5 bins.

Therefore, the discretization with **10 bins is better than the one with 5 bins** for this dataset and classification task.

T19. Submit your code (.py or .ipynb) on mycourseville.

Solution. There are two parts of the code for this homework.

1. The code for the basic Naive Bayes classifier (manually calculating the likelihoods and priors) can be found in the appendix **SimpleBayesClassifier**.
2. The code for the Naive Bayes classifier using histogram discretization and Gaussian distribution can be found in the appendix **homework-2-starter-code**.

If you've made it this far, **congratulations!** you've just created simple models that can help HR deal with one of their biggest problems. Simple, isn't it? This is a real world task with real implications, and I personally have been approached by big companies to help with this.

Classifier Variance

Recall, in class, we talked about the variance of a classifier as the training set changes. In this section, we will evaluate our model if we shuffle the training and test data. This will give a measure whether our recognizer is good just because we are lucky (and give statistical significance to our experiments).

OT4. Shuffle the database, and create new test and train sets. Redo the entire training and evaluation process 10 times (each time with a new training and test set). Calculate the mean and variance of the accuracy rate.

Solution. Using the process of shuffling the database and creating new training and test sets, we can evaluate the Naive Bayes classifier 10 times and calculate the mean and variance of the accuracy rate.

Note: I'm using random seed from 0 to 9 for shuffling the data and creating new training and test sets.

After performing the shuffling and evaluation process, we can report the mean and variance of the accuracy rate as follows:

Metric	Value
Mean Accuracy	0.8551
Variance of Accuracy	0.0001

    Computes mean and standard deviation for each feature in the dataset.

    Parameters:
    x (np.ndarray): The feature matrix, where rows are samples and columns are features.
    y (np.ndarray): The target array, where each element corresponds to the label of a sample.

    Returns:
    (gaussian_stay_params, gaussian_leave_params): A tuple containing two lists of tuples, one for 'stay' parameters and one for 'leave' parameters. Each tuple in the list contains the mean and standard deviation for a feature.
    """
